The finite difference, is basically a numerical method for approximating a derivative, so let's begin with how to take a derivative. The definition of a derivative for a function  $f(x)$  is the following Now, instead of going to zero, lets make  $h$  an arbitrary value.

The finite difference operator  $\delta_x^2$  is called a central difference operator. Finite difference approximations can also be one-sided. For example, a backward difference approximation is,  $\partial_x U \approx \frac{U_{i,j} - U_{i-1,j}}{\Delta x}$

Principle of finite difference method ●We have learned in Chapter 2 that differential equations are the equations that involve derivatives. ●Physically, a derivative represents the rate of change of a physical quantity represented by a function with respect to the change of its variable(s):  $f(x) \approx f(x + \Delta x) - f(x)$

Finite Difference Methods for Hyperbolic Equations. 3.1. Introduction. Most hyperbolic problems involve the transport of fluid properties. In the equations of motion, the term describing the transport process is often called convection or advection. E.g., the 1-D equation of motion is  $\rho \frac{du}{dt} + \rho u \frac{du}{dx} = -\frac{dp}{dx}$ .
