Fig. 2 Delivered steam pressure is regulated by balancing forces acting directly on the valve itself: the downward force caused by compression of the adjustment spring against the upward force from the secondary pressure acting against the underside of a bellows or diaphragm.. Note: The movements in the animation are slowed and exaggerated in order to show the opening and closing of the valve.

Steam headers should be drained in a similar way to steam mains, with a pocket suitably placed along the bottom of the manifold. A slight fall towards the end which houses the drain pocket assists drainage. Headers longer than 5 m may benefit from a drain pocket at either end. Float traps are best suited to handling fluctuating condensate loads.

To ensure steam pressure gauges are highly reliable, it is essential to use a steam gauge pigtail, which will prevent damage to the gauge from direct exposure to high steam temperatures. The pigtail allows steam to change phase from a gas into a liquid by dissipating the latent heat energy of steam and allowing the steam to condense, thus providing a loop seal of liquid.
