A large portion of the field of statistics is concerned with methods that assume a Gaussian distribution: the familiar bell curve. If your data has a Gaussian distribution, the parametric methods are powerful and well understood. This gives some incentive to use them if possible. Even if your data does not have a Gaussian distribution. It is possible that your data does

- [Instructor] Let's say that we have a random variable  $x$ . Maybe it represents the height of a randomly selected person walking out of the mall or something like that and right over here, we have its probability distribution and I've drawn it as a bell curve as a normal distribution right over here but it could have many other distributions but for the visualization sake, it's a normal one in ...

3 The Probability Transform Let  $X$  a continuous random variable whose distribution function  $F_X$  is strictly increasing on the possible values of  $X$ . Then  $F_X$  has an inverse function. Let  $U = F_X(X)$ , then for  $u \in [0;1]$ ,  $P\{U \leq u\} = P\{F_X(X) \leq u\} = P\{X \leq F_X^{-1}(u)\} = F_X(F_X^{-1}(u)) = u$ : In other words,  $U$  is a uniform random variable on  $[0;1]$ .

A big problem with transforming to achieve normality. Let's say all the other regression assumptions are reasonable, apart from the normality assumption. Then you apply some nonlinear transformation in the hopes of making the residuals look more normal. Suddenly, your previously

This chapter describes how to transform data to normal distribution in R. Parametric methods, such as t-test and ANOVA tests, assume that the dependent (outcome) variable is approximately normally distributed for every groups to be compared.

In that case transforming one or both variables may be necessary. Summary: None of your observed variables have to be normal in linear regression analysis, which includes t-test and ANOVA. The errors after modeling, however, should be normal to draw a valid conclusion by hypothesis testing. Note:

## **Impact of transforming (scaling and shifting) random variables**

In probability theory, a normal (or Gaussian or Gauss or Laplace-Gauss) distribution is a type of continuous probability distribution for a real-valued random variable. The general form of its probability density function is  $f(x) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$ . The parameter  $\mu$  is the mean or expectation of the distribution (and also its median and mode), while the parameter  $\sigma$  is its standard deviation.

A log transform would transform any of the components of the mixture to normality, but the mixture of normals in the transformed data leaves you with something that's not normal. Or there may be relatively nice transform, but not of one of the forms you'd think to try -- if you don't know the distribution of the data, you may not find it.
